HOW TO USE THIS HANDBOOK

Whether you’re a pilot or an educator — or both — you’ll find that this Pilot and Teacher Handbook is designed to effectively connect aviation and everyday classroom topics for middle and high school students. We’ve divided this book into three sections:

For Pilots: Here you’ll find guidelines to help you prepare for a day in class. We cover everything from how to arrange a classroom visit, to touring a local airport, as well as the steps you need to take as follow up, so that a first flight can be a reality for interested students.

For Teachers: We’ll help you take aviation straight into the classroom with easy-to-follow modules that can be used alone or in conjunction with a pilot’s visit. Each module highlights a common question people often ask about general aviation and ties the activities to key classroom topics.

Resources: This information is designed for pilot and teacher alike, to find additional materials on general aviation such as a reading list, web sites, and special offers to help you turn the dream of flight into a reality for you and your students.

The Aircraft Owners and Pilots Association (AOPA) represents the general aviation industry and its pilots. With more than 415,000 members, AOPA is the largest and most influential aviation association in the world. AOPA has proudly served its members through advocacy, education, and many other services since 1939.

AOPA would like to thank Jim and Karli Hagedorn for their generous sponsorship of the PATH to Aviation.

INTRODUCTION

Path to Aviation

Pilots, What Inspired You to Fly?

Was it the daily ride past your local airport on your way to school? Or a ride in an airplane with your grandfather or favorite uncle? Maybe it was the airline flight to a family vacation? Or was your passion sparked simply by staring at the blue skies and watching a jumbo jet fly overhead? However you started your adventure, sharing the dream of flying is one of the best gifts you can pass on to the next generation of aviators.

As a pilot, you’re part of a select group of Americans. Less than one-third of one percent of us know how to fly an airplane. That makes you special. But who will be there to foster a young person’s love of flying if he or she has no one in their lives connected to aviation? You are the answer. You can share your passion for flying and your knowledge with local students by volunteering to visit classrooms and talk with students about your experiences in aviation and potential careers.

Our schools rely immensely on volunteers like you to enrich classroom experiences and become mentors for young people. You can outline the challenges and rewards of flying whether for pleasure or as a professional career—while helping teachers bring excitement and energy to lesson plans. You know how aviation uses core subjects to make flying a reality. Help a teacher or student learn how to make the connection too.

The common denominator for all who start to fly is some kind of inspiration and contact. You can provide that. History class may seem boring until a student hears about Amelia Earhart and how she flew Eleanor Roosevelt from Baltimore to Washington, D.C., discussing current events along the way. Physics class takes on a whole new dimension when the problem involves determining how much jet fuel it takes an SR-71 to fly from Mojave, California, to Houston, Texas. And imagine how much fun English class would be if students had to spell out words phonetically like, “INDIA-FOXTROT-LIMA-YANKEE?” “I FLY!”

Take every opportunity you are given—create opportunities—to reach out to young students and encourage them to think about the joy of flying and how it fits into everything they must learn. You can plant the seeds of aviation by connecting it to history, math, science, communications, and so much more. Our schools today need all the help they can muster to keep students focused on learning. Aviation needs new flying enthusiasts and career pilots in our future to keep us strong. Together, we can turn dreams into reality and make learning practical yet fun.
MAKE THE CASE FOR AVIATION. For a pilot interested in sharing his or her experience with students, the road to the schoolhouse may not be so easy. Schools are under pressure to perform well, and administrators and teachers seek to link most classroom activities to the corresponding state’s educational standards. While pilots use math, physics, science, and communications skills every time they fly, it will be up to you to make this connection clear. Before you barnstorm into a classroom, get a feel for the parts of the curriculum that overlap with general aviation by visiting your state’s department of education or public schools web site. No one expects you to prepare an entire course, or even a lesson plan, but the research puts you in a better position to be a valuable resource to work with a teacher or class. Regardless of whether you fly professionally or for pleasure, you will be an instant hit—you’re a pilot! But in today’s competitive school climate, if you can provide sustenance instead of a “snack”, you stand a much better chance of breaking through.

MEET THE TEACHER
If you don’t have direct ties to a particular school or class, call a local middle or high school and ask about any upcoming career day, or other opportunities to talk to a class about aviation. If a teacher extends you an invitation—or once you have made connections with a particular teacher or principal—arrange a meeting at the school. This first contact is important to ensure your presentation is on target and appropriate to the class subject and age group. Allow the educator to ask any questions of you—including a description of your aviation background and training—prior to your presentation.

At this meeting, confirm the date and time of your visit and discuss any equipment requirements you have, such as a video monitor, overhead projector, and photocopier to make handouts. Find out how many copies the school needs if you plan to make them yourself. Teachers must order equipment in advance, and they may not have specialty equipment if you are bringing in a laptop for your presentation. You also should visit the room in which you will be speaking to get comfortable with the setting.

Be sure to discuss how the teacher might prepare students for your visit. Remember the parents: They are often the key to maintaining their child’s interest in aviation after you’ve left the classroom. Materials to take home can have a lasting impression.
FOCUS ON THE AGE GROUP

Every age group has different needs, expectations, and abilities. Middle and high school students have reasonable attention spans and have had some preparation in math and science that help them relate to your presentation. No matter the age, students will like something tangible to take away from your visit, even if it’s simply a paper airplane, an old chart, or a picture of a cool airplane.

FORM YOUR PRESENTATION

Make it personal! Share with students some insight into your world of flying. Talk about how you got started and the fun you’ve had as a pilot. Tell them about a time you flew somewhere very special to you. The look on your face and your body language as you tell these personal stories will make an impression.

If you had trouble with math in school, say so! If math makes more sense to you now that you are a pilot, be sure to share that with the students, too. Use an example of the simple math you might use to plan a flight if you’re addressing an age group developing those skills.

Bring aviation photographs, videos, slides, and aviation magazines from your collection. If you can, leave them behind for a display, or donate them to the school.

ESTABLISH YOUR EXPECTATIONS, AND BE READY FOR THEIRS

You’re going back to school, but in a different role. Be sure to arrive early enough to set up your presentation. During your initial discussion with the teacher find out if you need to sign in at the main office or show identification. Once you’re in the classroom, test your equipment and be sure your props and notes are in order. Here are some tips for managing the presentation:

- Help students understand why you are there. Everyone has expectations, so be sure to state yours. If you want, suggest that you will take questions throughout your presentation. You can put everyone at ease by suggesting how you would like them to respond: “When you raise your hand and I call on you, please tell me your name.”

- Students will judge you by how you act, and what you say and how you treat them. Show respect to the teacher and students. Students won’t respect someone who doesn’t respect them. You can address your audience as “ladies and gentleman,” especially in high school, to set the tone.

- Remember that the younger the age group, the more activity you need in order to keep their attention. It’s helpful to show photographs, videos, or run a flight simulation.
Get students involved with the presentation. Engage them with hands-on projects. Have student volunteers help hand out materials, hold models, and answer questions you ask them.

When you ask for participation, try to encourage everyone. Don’t exclude anyone.

Be careful using jargon. We pilots have our own language. Be sure you translate any aviation terms into plain English.

Dress the part! If you fly professionally, wear your uniform. If you fly for fun, you can wear a flight suit, coverall, shirt with airplane embroidery or an N-number, or flight jacket and, of course, an AOPA cap.

Be enthusiastic! Make the presentation fun and positive. Smile! Don’t belabor any negatives; address them and move on. It’s important for these students to know for certain that you love flying and being a pilot.

Be sure to pace yourself to accomplish your program within the time allotted. Save time at the end for questions and answers, about 15 minutes, depending on the group size.

**FOLLOW UP WITH THE CLASS**

You want to get these students out to the airport if possible. So start by writing a thank you note to the teacher, principal, and others at the school who supported your efforts.

Don’t end your dialogue with students when you leave the classroom. Ask them to write to you with any questions. Leave paper and self-addressed, stamped envelopes, or your email address. Some students may be intensely interested in aviation and want to meet with you again—perhaps to see a real airplane or take an introductory flight. This may prompt the teacher to work with you to develop a field trip or invite you to return for another session.
BASICS OF FLIGHT. Even though you can’t bring a full-size airplane into the classroom, you can make your presentation a hit by starting with a model of an airplane, going over the parts, and covering the basic theories of flight. Start simple and encourage students to participate: “What do the wings do? Wings produce lift.” “What does the propeller do? It produces thrust.” Secondary students should all be familiar with gravity, but what about drag?

While in the classroom, you also can lead the students in a project to demonstrate flight control concepts and the four forces of flight. Have everyone build a paper airplane. Add paperclips for weight and ask the students how they think it will affect the airplane’s ability to fly.

Beyond the model airplane itself, if you have access to a cockpit mockup or poster (which you might be able to borrow from your local flight school) you can use it to show students around the instruments, flight controls and radios. Perhaps point out how our standard navigation radios used for flying share the same frequency as a basic FM radio; aviation just starts at 108 MHz where FM radio ends.

Some students may be familiar with computer-based flight simulator programs. If you are able to bring a laptop, and you or the school have an LED projector, use the program to demonstrate maneuvers and let students have a try at the controls.

Like the paper airplane, your presentation does not have to be high-tech. You can bring other props into the classroom, such as headsets, your flight bag, charts and hand-held flight computers. If you have old sectionals, pass them around for students to look at and find different landmarks. Print out the day’s radar chart and make color copies for the students to forecast the next day’s weather. Ask them how their predictions might affect a flight.

CLASSROOM TOOLS

Go to www.aopa.org/path and check out the “Classroom Tools” section for a PowerPoint slide presentation that you can use during your classroom visit. Feel free to use the entire presentation or just select slides. Links to a gallery of photos for your use also can be found.
WHAT TO COVER:
- Parts of the airplane
- Four forces of flight: lift, drag, thrust, and weight
- Control surfaces, devices, and their functions
- How changes to the control surfaces or Center of Gravity change the airplane’s flight
- How different airplane designs reduce weight and drag
- Tools a pilot uses in flight

WHAT TO BRING:
- Aircraft model
- Cockpit or instrument panel mock-up
- Paper, paper clips, and tape for building paper airplanes (see Module 3)
- Laptop with flight simulator program
- Flight bag with headset, charts, kneeboard, flashlights, handheld GPS and/or transceiver
- Old sectional charts
- Weather graphics printouts

WHY IT WORKS
This is your opportunity to introduce the magic of flight to students and their teacher. You’re talking with middle or high school students, so give them a little credit and follow their lead. Give them ample opportunity to ask questions throughout your presentation and adjust your answers to meet their level of understanding.
FLYING IS FUN. Here’s your chance to demonstrate the best parts of flying. If possible, have a passenger videotape a local flight with you. Be sure to have your passenger film local landmarks from the air—especially the school, sports arenas, and parks—so that you can point them out during your presentation.

Show a video of a pilot doing aerobatics, taken either from the cockpit or the ground at an airshow.

Display pictures of your local airport; if you have access to a large, overhead shot of the airport layout, use that. Talk about the kinds of airplanes that fly from your airport, and show pictures of these different types. If your airport has a control tower, show pictures of the tower and some of the controllers who work there—especially if you can show them talking on the radio to pilots.

Talk about the different jobs available in aviation and specifically the various pilot jobs. Maybe students are only aware of airline pilot jobs, but there are many more: flying executives as a corporate pilot, flying helicopters as a medevac, Customs, or Coast Guard pilot, flying search and rescue missions as a member of the Civil Air Patrol, fighting fires as a tanker pilot, teaching people how to fly as a flight instructor, and selling airplanes to people as a demonstration pilot—to name a few.

Bring photos of the places you’ve flown as a pilot. Mark up a chart with your longest cross-country flight and show them a flight log from that journey. Some students have yet to leave their hometown, so even a trip to your state capital may seem like a trip around the world to them.

Talk about how you learned to fly, how you got started, where you went to learn, and how long it took you. Explain how nearly anyone can learn to fly who meets the age and English-speaking requirements—even people with disabilities fly.

WHAT TO COVER:
- Pilots in flight—you, airshow pilots, military demos
- Your local airport
- Careers in aviation
- Places you’ve been
- Learning to fly

WHAT TO BRING:
- Photos and/or videos of airports and airplanes
- Photos from flights you have taken
- Aeronautical charts of the local area
- Textbooks, logbooks, and other flight training materials
- Your pilot and medical certificates
FIELD TRIPS CAN BE GREAT to highlight different kinds of aircraft. If you are able to arrange a class visit to the airport, be sure to plan ahead with fellow pilots and your local FBO to show high-wing and low-wing aircraft, maybe even a taildragger. Make arrangements so each student can sit in the cockpit of at least one airplane—one they might fly during flight training. Work with their teacher to ensure proper supervision. Remember that when you fly into Class B airspace, you need to get a clearance. So when planning a field trip to the airport, keep in mind that most children need a clearance—from mom and dad—to join you for a day of adventure, even on the ground.

HOW IT WORKS

Like anyone, when young people approach an airplane, they want to know what specific parts of the airplane do. They point to the flaps and ask questions one on top of another: “What are these?” “How do they move?” “Why do pilots use them?” Then, before you have a chance to finish, they’re on to the ailerons, the elevator, the rudder, and the antennas sticking up from the fuselage. The airplane is a fascinating machine, and by walking them down the flight line you can open their eyes to the variety of airplanes that fill the skies.

If at all possible, pre-arrange to find a cockpit they can sit in. If they can move the control yoke, so much the better, but at least put them in a position to see the nerve center of the airplane. Help students imagine themselves as a pilot.

From the airplane, move to either the control tower (if you have access to one at your field) or to a fixed-base operator (FBO), where the students can see how the process of getting an airplane in the air develops.

Because of security concerns and regulations, you must coordinate a visit to the control tower in advance.

At the control tower, if you pick a slower-work time, most controllers are happy to take a few moments to escort the students to the tower cab and show them their perch and what they do. Up there, students can see the radios that controllers use to talk to pilots, the monitors they use to sequence arrivals and departures, the flight strips they use to track airplanes on the ground and in the air, the telephones to call ATC and flight service, and the light gun that they use to signal airplanes without radios.
At the FBO, you can visit with the staff about how many pilots they see on a given day, and where they’ve flown in from. You can point out to the students the line staff who service the airplanes. Arrange in advance to stop by the maintenance hangar to talk to mechanics about the work they do. If you can find an airplane with the cowling off, or an engine on a test stand, have the mechanics point out the parts of the engine and how it turns the propeller.

No matter what your destination is at the airport, it’s best to save the trip for a small group of students. No more than six to eight students per adult, depending on age. If you have a larger group, enlist other pilots to help you, and split the group up so that each child has good access to every person and site at which you stop. And it’s easier to keep a small group safe on an active ramp or in a shop.

**PLACES TO GO:**
- Airplane in a hangar
- Airplanes on the ramp
- Airplane in the maintenance shop
- Air Traffic Control tower (advance coordination required)
- FBO facility

**PEOPLE TO MEET:**
- Pilots (both GA and commercial)
- Flight instructors
- FBO front desk staff
- FBO line staff
- Airframe and powerplant mechanics
- Airport manager
- Air traffic controllers
The young people you speak with may not have thought ahead to what they want to do after they graduate. Many of them will have considered their options and have a good idea of what career path they want to pursue, especially if you address high school juniors and seniors.

As one of the fastest growing segments in the transportation industry, aviation is a huge resource for jobs in virtually every major skill area. With advancing technology—such as glass cockpits, GPS, ADS-B, WAAS, and datalink weather and traffic—large numbers of talented people will be needed to keep up with ever-expanding opportunities.

We need more pilots to sustain the aviation industry for the future, but careers in aviation are more varied than just pilots. The numbers tell the story: As domestic air travel returns to its pre-September 11 levels, the general aviation fleet is growing at just over one percent each year and the turbojet fleet is growing at about 3.7 percent, thanks to projected demand for very light jets and traditional business jets. The U.S. has approximately 600,000 pilots—of all types and ratings—and there are millions of other jobs in the aviation industry.

In addition to well-known careers in the cockpit of both commercial and general aviation aircraft, young people might consider other important careers related to flying. For example, emergency medical services, law enforcement, news and traffic reporting, surveying and mapping, agricultural services, pipeline patrols, forestry and wildlife management. They also might consider ground support roles, avionics, maintenance and design.

When you can visit with secondary students in their classroom, you are reaching them at a perfect time to plant the seeds for a career in aviation. Urge them to continue their studies, because it can only help them prepare for the training they will need after

**AVIATION ACRONYMS**

GPS: Global Positioning System
ADS-B: Automatic Dependent Surveillance - Broadcast
WAAS: Wide Area Augmentation System

AS A PILOT, you might fly for recreation, business, or as a career. When aviation is your job, it might not be difficult to describe how you found your calling, what steps it took to attain your career goals, and what opportunities are for growth. Even if flying is your avocation, rather than your profession, like many of us, you are exposed to a variety of individuals who have made a career in aviation. Consider every person you call upon in the course of planning and executing a flight: what do they do and how have they made aviation their life’s work?
high school, either in a technical, vocational or university environment.

Check out the inside-back cover of this handbook for AOPA’s contact information and request “Aviation Careers,” a brochure for students, guidance counselors, parents, and anyone with an interest. “Aviation Careers” outlines different jobs and their educational requirements and identifies potential employers. Some of the careers you can discuss include:

- Aerospace engineer
- Agricultural pilot
- Air traffic controller
- Aircraft manufacturing technician
- Airframe and powerplant mechanic
- Airline pilot
- Airport manager
- Avionics technician
- Cargo pilot
- Computer programmer
- Corporate pilot
- Customer Service Representative
- Financial manager
- Flight attendant
- Flight dispatcher
- Flight instructor
- Meteorologist
- Operations chief
- Security officer

A corporate pilot prepares his airplane for flight.
A SPECIAL OFFER FOR STUDENT (AND PROSPECTIVE) PILOTS—FREE FROM AOPA.

If you’re currently training for your private pilot certificate or about to start training, you have an exclusive opportunity to receive a free, no-risk AOPA student trial membership with valuable training tools and key learning resources to support you during your flight training.

In fact, students who are AOPA members are three times more likely to get their private pilot certificate.

When you become a student trial member, you can…

- Help understand new concepts, learn key aviation terms and more through our online library of learning resources at ft.aopa.org.

- Talk directly to one of our in-house CFIs and pilots available by phone or email to answer your flight training questions.

- Enhance your knowledge and skills with online pilot training support including courses, quizzes, and learning aids.

- Learn additional training techniques and tips with ePilot Flight Training, our weekly newsletter dedicated to student pilots.

- Access online flight planning resources, including AOPA’s online Airport Directory and Internet Flight Planner—great for double-checking your calculations.

PLUS SIX FREE ISSUES OF FLIGHT TRAINING MAGAZINE WITH PRACTICAL ADVICE AND TIPS FROM EXPERIENCED PILOTS AND INSTRUCTORS

START YOUR FREE TRIAL NOW BY GOING TO FT.AOPA.ORG/FTFREE. ENROLLMENT IS QUICK AND SIMPLE AND YOU’LL GET IMMEDIATE ACCESS TO AOPA’S ONLINE TRAINING TOOLS AND RESOURCES.
SINCE YOU CAN’T TAKE A CLASSROOM IN THE AIR,

you can duplicate some of the sensations associated with controlling an airplane with this activity.

MATERIALS:

Wheelbarrow
Model airplane

WHAT TO DO:

► Divide the students into teams of two.

► Each team takes a turn at the wheelbarrow: One person sits in the wheelbarrow, holding the model airplane “straight and level,” and the other person takes the handles (control yoke) of the wheelbarrow to manipulate it.

► As the person in the wheelbarrow banks the airplane left and right, the person at the “controls” of the wheelbarrow tips that person (gently) left and right. This simulates turning the control wheel or stick in the airplane into left and right banks, and gives the person in the wheelbarrow a similar sensation as they would feel in the airplane when the control wheel actuates the ailerons on the wings.

► As the person in the wheelbarrow pitches the airplane nose up and nose down, the person at the controls also pitches the wheelbarrow back and forward (never coming close to dumping the passenger inside!). This simulates the feeling when a pilot pushes forward or pulls back on the yoke, activating the elevator on the rear of the airplane.

► As the person in the wheelbarrow yaws the airplane, turning the nose left and right, the person at the controls spins the static wheelbarrow left and right on its front wheel. Again, this simulates what it feels like to yaw (maneuver the airplane about its vertical axis) the airplane with the rudder pedals inside the cockpit.

► In order to make a “coordinated turn” the pilot must use bank to start the turn and yaw to align the airplane’s fuselage with the direction of the turn.

► Demonstrate how it would feel for these control inputs to work together, using the model airplane (by the person in the wheelbarrow) and the wheelbarrow itself (by the person at the controls).

Note: Adapted from “Women/Leaders Take Flight” seminar, presented by Linda Castner.

NOTE:

If you cannot find a wheelbarrow—or school policy won’t allow students to climb into one—find a shallow cardboard shirt or gift box and place a doll or action figure in the open box. Students can manipulate the box like the wheelbarrow to see how the controls might work.
A Piper Archer flies over suburban Maryland.
One of the challenges you probably have is putting a fresh face on a subject you may have covered many times. It can be a daunting prospect, but there is one topic that can take you anywhere you want to go: aviation.

Bringing aviation into the classroom is a great way to combine the fun of aviation and learning. It’s important to have the right tools available to help you apply the lessons of flight to your required curriculum.

We’ve put together 11 modules that answer common questions about flying and tie basic aviation to the subjects like math, physics, history, and science. Use these activities independently or in conjunction with a visit from a local pilot.

If you are thinking about a field trip, research a nearby aviation museum on the Internet, and, if you can, enlist any interested pilots to go with your group for additional insight—and crowd control!

And don’t forget aviation’s ties to space flight. Your school curriculum may already contain a section on space; you can use aviation as a springboard to demonstrate how the human race started its foray into the atmosphere—and beyond!

You can spark the interest of your students by introducing them to aviation—and that’s our goal at the Aircraft Owners and Pilots Association (AOPA). We encourage you to follow up on this interest and help them achieve their goals by using the resources at the back of the handbook. There you’ll find a comprehensive list of resources on aviation, as well as ways to encourage them to consider the many career opportunities in aviation.

Feel free to use the modules as you wish: photocopy them, add to them, and take what you need from them. You’ll find complementary student worksheets at www.aopa.org/path.
How do pilots understand each other?

LEARNING OBJECTIVES:
► Students will explain how and why pilots use the phonetic alphabet
► Students utilize the aviation phonetic alphabet in both written and spoken form

CORE SUBJECTS: ENGLISH, SPELLING, LANGUAGE

LEARNING THE LANGUAGE OF AVIATION
is the first step in understanding people who fly. All pilots know that clear communication is key to staying safe in the air. Pilots need to talk to other pilots and air traffic controllers in a concise way that everyone can understand. Miscommunication can cause problems when they are 10,000 feet in the air, taxiing across a runway, and everywhere in between.

While the language of aviation worldwide is English, pilots have developed a sort of universal code to help keep their communications as clear as possible to anyone listening. Pilots use a phonetic alphabet when saying anything they need to spell out, substituting a particular word that begins with the letter they need. Civilian and military pilots around the world—from Albany to Zurich—use the same words for each letter, such as “alpha” for “A” and “zulu” for “Z.”

Add a twist to your next English or spelling lesson. Teach students the phonetic language used by pilots. Explain the need for clear communications regardless of native language or regional accent.

Here is the phonetic aviation alphabet:

<table>
<thead>
<tr>

</tbody>
</table>

All other numbers use standard pronunciation.

PRACTICAL USES

Pilots most frequently use the phonetic alphabet to identify specific airplanes. In the U.S. most aircraft are registered with the Federal Aviation Administration. They provide what is often referred to as the "N" number, since all U.S. airplane registrations start with that letter. An aircraft’s N-number is made up of some combination of letters and numbers painted or affixed to the airplane, similar to a car’s license plate, but large enough to be visible when the airplane is in flight.
TEACHERS:
From this activity, students will learn how to use the phonetic alphabet.

SPELL OUT THE FOLLOWING WORDS USING THE PHONETIC ALPHABET:
1. PILOT ________________________________________________
2. AIRPLANE __________________________________________
3. SCHOOL _____________________________________________
4. Name of your school mascot ___________________________
5. Your city or town _____________________________________
6. Your first name _______________________________________

HOW WOULD YOU IDENTIFY THE FOLLOWING AIRCRAFT WHEN TALKING TO AN AIR TRAFFIC CONTROLLER ON THE RADIO?

7. ____________________________
8. ____________________________
9. ____________________________
10. ____________________________
Close-up photo of a Mooney aircraft with the engine cowling removed.
LEARNING OBJECTIVES:
> Students will construct paper airplanes in preparation for control surface experiments
> Students will identify the parts of an airplane and be able to explain their role in the operation of the airplane

CORE SUBJECTS: MECHANICS, SCIENCE, AERODYNAMICS

THE AIRPLANE IS ESSENTIAL to human flight. It is a heavier-than-air vehicle, powered by an engine that travels through the air via the forces of lift and thrust. Its pieces provide clues to what makes an aircraft move up and down, left and right and side-to-side. Your students may be surprised to learn that small, single-engine airplanes and large jetliners have essentially the same basic parts. They just get bigger as the size of the airplane increases.

Use this as a reference for other activities in this handbook.

THE MAIN PARTS OF AN AIRPLANE
1. Propeller
2. Landing Gear
3. Right Wing Strut*
4. Wing
5. Right Wing Aileron
6. Right Wing Flap
7. Fuselage
8. Horizontal Stabilizer
9. Vertical Stabilizer
10. Rudder
11. Elevator
12. Left Wing Flap
13. Left Wing Aileron
14. Door
15. Fuel Tanks
16. Windshield
17. Engine Cowling

* Left wing strut hidden under wing in this diagram
**What are the parts of an airplane?**

**Parts of an Airplane That Make It Fly**

**Propeller** – A propeller is a rotating blade on the front of the airplane. The engine turns the propeller, which pulls the airplane through the air.

**Wings** – Wings are the parts of airplanes that provide lift. They also support the entire weight of the aircraft and its contents while in flight.

**Flaps** – Flaps are the movable sections of an airplane’s wings that are closest to the fuselage. They move in the same direction on both wings at the same time, and, by creating drag and lift, enable the airplane to fly more slowly.

**Parts of an Airplane That Help Control Direction of Flight**

**Ailerons** – Ailerons are the movable sections on an outer edge of an airplane’s wings. They move in opposite directions (when one goes up, the other goes down). They are used in making turns by controlling movement around the **longitudinal axis** (an invisible line through the airplane from the nose to the tail).

**Rudder** – The rudder is the movable, vertical section of the tail that controls lateral (side-to-side) movement along the **vertical axis** (an invisible line through the airplane perpendicular to the longitudinal axis). When the rudder moves in one direction, the aircraft nose moves the same direction.

**Elevator** – The elevator is the movable, horizontal section of the tail that causes the airplane to climb and descend. When the elevator moves one direction, the nose moves in the same direction (up or down). This movement is along the **lateral axis** (an invisible line that runs from wing tip to wing tip).

**Other Parts of an Airplane**

**Fuselage** – The fuselage is the central body of an airplane, designed to accommodate the pilot/crew and the passengers and/or cargo.

**Cockpit** – In general aviation airplanes the cockpit is the space within the fuselage where the pilot sits and controls the airplane.

**Landing Gear** – The landing gear is underneath the airplane and supports it while on the ground. The landing gear usually includes two main wheels and a nose- or tailwheel.
**LEARNING OBJECTIVE:**

- Students will be able to observe, explain, and analyze the effects of an airplane’s control surfaces.

**CORE SUBJECTS: AERODYNAMICS, MECHANICS, ENGINEERING**

**FLIGHT CONTROLS OF AN AIRPLANE**

are surprisingly simple. The systems may get more complex on larger airplanes, but the basic principles are the same for anything from a trainer aircraft to the largest of airliners.

You may have wondered why airplanes bank (lean to one side) as they turn. The reason is that airplanes turn by directing the lift of their wings more to one side or the other. This is done by moving control surfaces on the wings known as ailerons. When you turn the control wheel (also known as the yoke), the aileron on one wing deflects downward, while the aileron on the other wing goes up. This increases and decreases, respectively, lift on the wings.

Climbing and descending is directed through use of movable control surfaces on the horizontal portion of the tail. Appropriately enough, they are called elevators and are activated by pushing the control wheel forward or pulling it back.

The third basic control for flying an airplane is the rudder. Contrary to what you might expect, the rudder alone does not steer the airplane but rather serves the purpose of properly aligning the airplane in flight. The pilot controls the rudder’s movement with rudder pedals on the floor of the airplane and also uses them to steer the airplane’s nosewheel or tailwheel when on the ground.

*Note: adapted from “You Can Fly!” by Gregory N. Brown and Laurel Lippert*
FLIGHT CONTROLS OF AN AIRPLANE

YOKE CONTROLS

When you turn the yoke left, the left aileron goes up, the right aileron goes down (black arrows), the left wing goes down (white arrow), and the airplane banks left.

When you turn the yoke right, the right aileron goes up, the left aileron goes down (black arrows), the right wing goes down (white arrow), and the airplane banks right.

When you push the yoke forward, the elevator goes down (black arrow), forcing the tail up, and the nose goes down (white arrow).

When you pull the yoke back, the elevator goes up (black arrow), forcing the tail down, and the nose goes up (white arrow).

RUDDER PEDAL CONTROLS

Push the left rudder pedal and the rudder on the tail moves left (black arrow), forcing the tail to the right and the nose moves left (white arrow).

Push the right rudder pedal and the rudder on the tail moves right (black arrow), forcing the tail to the left and the nose moves right (white arrow).
TEACHERS:
From this activity, students will learn how control surfaces—the moving parts on the wing and tail—control which way an airplane turns and moves through the air.

MATERIALS:
Sheet of paper
Paper clips
Room to throw

TO DO IT:
Folded Paper Glider

1. Fold paper in half lengthwise and crease.

2. Fold down the corner of one side so the edge is even with the folded side of your original crease. Flip paper over and repeat to form a point.

3. Fold down the angled edge on one side so it is even with your original fold. Flip and repeat. You should now have a more narrow point.

4. Make a third fold that brings your new top edge even with the bottom of your original fold.

5. Push up the wings so they are perpendicular to the body of your airplane. Try launching your airplane.

Tip: If it seems “nose heavy” use paperclips near the rear of the airplane to add weight and help keep the nose up. You may need 2 to 3 paperclips.
ACTIVITY: Building a glider

Control Surfaces – Up and Down

Once you have gotten your airplane to fly relatively straight, gently tear the back edge of each wing to create elevators. One-half to three-quarters of an inch should be enough.

Bend your elevators up slightly and see what impact it has on the flight path. Bend them down and try again.

(Tip: Down position should cause the nose to go down faster. Up should help your airplane ascend or stay aloft longer.)

Look for modest changes in float direction. The average paper airplane only stays aloft for a few seconds.

When the pilot wants the airplane to climb, he moves the airplane controls so that the elevators tilt up in the same way that you folded back the edges of your glider. The air hitting the elevators pushes the tail of the airplane down, tilting the nose upward, so the airplane can climb.

Control Surfaces – Right and left

Now try the rudder or vertical fin. Tearing your elevators should have left you with a 1/2 - 3/4 inch portion of your airplane’s body that can be folded left or right. Try folding it slightly left or right and test the impact on your airplane’s flight path. Left or right folds should send your airplane left or right, respectively.

UP AND DOWN

RIGHT AND LEFT
LEARNING OBJECTIVES:
► Students will be able to define and explain the four forces of flight (lift, drag, thrust, weight)
► Students will analyze and evaluate the creation of lift using a paper airfoil experiment

CORE SUBJECTS: PHYSICS, AERODYNAMICS

WHEN AN AIRPLANE PASSES OVERHEAD
its flight looks effortless. You probably wonder how gravity allows something that large to stay aloft. An airplane is a machine that balances the forces of gravity with lift to make it fly.

Gravity acts on the **weight** of the airplane in flight just as it does on people and objects on the ground. **Lift** overcomes gravity and allows the airplane to fly. Lift is created when the forward motion of the airplane causes air to flow over those wings (also called an airfoil).

Several principles combine to explain how lift is created. These include Newton’s laws of motion and Bernoulli’s principle on the motion of fluids.

You may be familiar with Newton’s third law of motion that states “for every action there is an equal and opposite reaction.” As the air flows over a wing’s upper surface, it bends downward. The “opposite reaction” is a push upwards, which is part of lift.

Also, air flowing over the curved upper wing surface travels faster than the air flowing under the flatter bottom surface of the wing.

A Cirrus SR20 flies over a dense forest.
Another way of looking at the generation of lift is to apply Bernoulli’s principle. As the air flows around the wing, an area of low pressure forms over its upper surface, and an area of relatively high pressure forms below the wing. The difference in pressure creates lift.

Most small airplanes have engines and propellers mounted in the front. The power produced by the engine is translated into thrust by the propeller, which pulls the airplane through the air. You feel a similar kind of thrust when a driver pushes the accelerator pedal in a car.

Thrust also works to counter the effects of drag, which is created by resistance against all of the surfaces of the airplane that impact the wind (and the development of lift). If you’ve ever been on a roller coaster and waved your arms as you sped along the track, or held your arm out an open car window, you have felt the drag created by air resistance.
TEACHERS:
From this activity, students will learn how the shape of an airfoil influences how well that airfoil develops lift.

MATERIALS:
- Paper
- Tape
- Plastic straw (cut in thirds)
- String
- Scissors
- Single-hole punch
- Electric box fan

TO DO IT:
- Bend the paper in half without creasing the fold.
- Punch a hole in the paper through both sides of the paper. Where you place the hole will determine the shape of your airfoil, or wing.
- Slide the straw through the holes and secure the straw to the paper with tape.
- Look at the wing from the side. Can you guess how well it will create lift, based on what you have just learned about Newton’s and Bernoulli’s theories?
  - Insert the string through the straw so that the airfoil can slide up and down on the string freely. Hold both ends of the string so that your airfoil does not fall off.
  - Set up the fan so that you can hang the airfoil in the air stream. With the fan off, position the airfoil and hold it so that it is perpendicular to the airflow, just as an airplane might fly its wing through the air.
  - Holding both ends of the string, turn the fan on low, and watch the airfoil to see if it rises on the string—a sign that lift is being produced.
  - Try different speeds on the fan, and various airfoils created by other students. Compare how well they work with the shape of each airfoil.

Straws can be inserted at different points to change the airfoil shape.
A Piper 6X lifts off the ground to start its flight.
Aircraft engineers set design limits on airplanes before they leave the factory, and these specifications tell the pilot how much weight the aircraft can handle—whether that weight is represented by people, bags, or fuel. Pilots carefully calculate the weight that they put on the airplane before they take off. Because if they don’t, the results can be grim.

Not only does the total weight have to be less than certain absolute limits, it can’t be put in the wrong place either. Ever try to jam a heavy load into the trunk of a car, only to watch the rear end sink to the axle? That’s not good for the car, to be sure, but a similarly out-of-kilter condition bodes even worse for an airplane.

An airplane balances on two points as it flies through the air, its center of gravity (CG) and its center of pressure or center of lift. The center of pressure is determined by where the total lift created by the wings is concentrated, an average of all the lift vectors emanating from the wing’s upper surface. Likewise, the CG is the fulcrum point of balance for all the weight on board the airplane, and the airplane itself (including the wings, the engine, and the fuel).

The center of pressure and the CG work in conjunction to determine the airplane’s longitudinal or pitch stability. An airplane is typically designed so that its center of pressure is located aft of the CG. This creates a situation in which, if the airplane’s nose is
abruptly pitched downward, the aerodynamic forces on the airplane will cause it to pitch back up, returning it to level flight.

The CG of the empty airplane is usually located somewhere along the airplane’s fuselage near the intersection of the cabin and wings; in most cases this empty CG is close to an optimum CG for the airplane. The farther a weight is placed from the CG, the more it can move the CG away from the optimal position. This is why the fuel tanks are often located near the empty CG of the airplane, so they can be filled without adversely affecting the CG. Consequently, as the airplane uses up the fuel, the change in weight doesn’t affect the airplane adversely in flight.

Airplanes have a CG range in which normal operations are possible. If you put a heavy weight near the tail of the airplane, and thus take the airplane out of its operational CG range, the airplane may be too nose-high and therefore difficult or impossible to control. On the other hand, if you move weight too far forward, and ahead of the operational CG range, you may make the airplane so nose heavy that you cannot pull back on the controls hard enough to lift off the runway on takeoff.

Either way, too much weight or too much weight in the wrong place can be hazardous to flying an airplane.

The weight of the pilot and any passengers affects the handling of an airplane.
Can an airplane be too heavy to fly?

The center of gravity is affected by where weight is placed. Each of these airplanes distribute weight differently based on the location of the passengers, baggage, and fuel.
ACTIVITY: Weight and gravity

TEACHERS:
From this activity, students will learn how to determine the center of gravity of an object. They’ll also learn how the center of gravity can shift when weight is placed in different locations on the same object.

MATERIALS:
Yardstick or ruler
Two rolls of masking tape
Stickers to label different points on the yardstick (tape will work too)

TO DO IT:
If an object weighs anything, it has a center of gravity or CG. As a reminder, this is the fulcrum point at which all the weight in an object balances. It is harder to find the CG on an irregular-shaped object like an airplane, but pilots must be aware of where the CG is during flight and exactly how changes in where weight is placed can affect the CG.

Engineers provide an optimal CG that provides the best overall performance of the airplane. While the placement of fuel is held constant by the location of the fuel tanks, engineers also provide pilots with the best options for placing weight, such as passengers and cargo, so that the CG does not move too far from its optimal position. See for yourself the effect of weight movement on the CG.

- Balance the yardstick on your finger until it hangs evenly. Mark this point on the yardstick with masking tape and label it CG1.
- Tear off a long enough piece of masking tape from one roll to affix the other roll of tape to the yardstick. Pick any point.
- Try and balance the yardstick on your finger at CG1. What happens? Now find the new CG for the yardstick. Mark it CG2.
- Take the same roll of tape and move it somewhere else along the yardstick away from CG1. Find the CG and mark it CG3. The yardstick with one roll of tape attached weighs exactly the same. Is the CG in the same place now that the weight has shifted? If it has moved, how far has it moved, relative to how far the weight moved?
- Have students take other common objects around the classroom and balance them to determine the CG.
What do all those gauges do?

LEARNING OBJECTIVES:
- Students will be able to identify and explain the purpose of the six basic flight instruments
- Students will determine the flight condition of an airplane by interpreting indications on flight instruments

CORE SUBJECTS: EARTH SCIENCE, ATMOSPHERIC SCIENCE

ALTITUDE, ATTITUDE, AND SPEED
are just a few of the things pilots monitor during every flight. Pilots initially learn to control the airplane by looking out the window and using the horizon as reference. Most airplanes, however, have an array of gauges and indicators, known as flight instruments, in a panel similar to the dashboard of a car. The panel of flight instruments provides the pilot with critical information about his or her airplane while flying. You can use the basic gauges of an aircraft to introduce your students to the concepts of airspeed, altitude, attitude or position, as well as how to use a compass.

SIX INSTRUMENTS COMMON TO MOST GENERAL AVIATION AIRCRAFT:

AIRSPEED INDICATOR
A gauge that displays the airplane’s speed through the air, based on the difference between ambient air pressure and ram air pressure. Typically shows airspeed in knots (nautical miles per hour) or in miles per hour.

ATTITUDE INDICATOR OR ARTIFICIAL HORIZON
An indicator that shows whether the airplane is pitched up or down, or banked (tilted) left or right. Here the orange bars indicate wing position relative to the ground as shown by the white line.
What do all those gauges do?

**Altimeter**

A highly sensitive barometer that shows an airplane’s altitude above sea level by measuring ambient pressure. The large numbers mark hundreds (long hand) or thousands (short hand) of feet.

**Heading Indicator OR Directional Gyro**

An indicator that displays aircraft heading, based on the 360-degree compass rose. The pilot sets the heading indicator based on the aircraft’s magnetic compass prior to taking off, and checks it against the compass in flight to ensure it stays accurate.

**Turn Coordinator**

A gyro-based instrument that shows the tilt of the wings. The position of the ball indicates if the airplane is in a coordinated turn. A turn is “coordinated” if the rate of turn is appropriate for the amount of bank angle.

**Vertical Speed Indicator**

An instrument sensitive to changes in ambient air pressure. It takes the rate of change and displays it as rate of climb or descent. Reads in hundreds of feet per minute.

**Definitions**

**Ambient air pressure:** The pressure of the air that is around you and the aircraft. Air pressure decreases as altitude increases, so the changes in ambient air pressure affect the aircraft’s altimeter.

**Ram air pressure:** The pressure of air as it is forced into a forward facing inlet. In general aviation, when the airplane moves forward, air is forced into an instrument called a pitot tube that is affixed to the wing. This ram pressure is compared against the undisturbed air in a static port to determine the airspeed of the aircraft.
An electronic flight display (EFD, a.k.a. “Glass Cockpit”) is a system of digital instruments using multiple liquid crystal display (LCD) screens that replace the traditional arrangement of individual instruments. Numbers in photo refer to instrument descriptions on pages 33-34.
**TEACHERS:**

From this activity, students will learn how to read the instruments and establish relationships between the indications on the instruments and the airplane's flight path.

**TAKE A LOOK AT THE FOLLOWING PANEL AND SEE IF YOU CAN FIGURE OUT WHAT THE INSTRUMENTS ARE TELLING YOU.**

**QUESTIONS:**
1. What is the airplane's indicated airspeed?
2. At what altitude is the airplane?
3. Is the airplane in a turn? What two instruments can you look at in order to know?
4. Is the airplane climbing or descending? What instrument(s) are you looking at in order to make this conclusion?
5. What direction is the airplane headed at this moment?
6. Based on your answer to Question #3, is the airplane's heading changing or staying the same?
7. If power has remained constant, based on your answer to Question #4, do you think the airspeed is increasing, decreasing, or remaining constant?
8. How long will it take the airplane to descend 1,000 feet?
When pilots fly their airplanes, they too become inextricably connected to the "ocean" of air around them. So pilots must study the ways weather distributes the cold and heat, forms the wind, and creates the precipitation we experience on the ground as rain, snow, and sleet.

Students have been affected by changes in weather patterns since they were little and their parents either lathered them with extra sunscreen on a sunny day or bundled them up with an extra sweater during a snowstorm. Teaching weather, its causes and effects, does not have to be a theoretical lesson of one invisible air mass hitting another invisible air mass. Place an airplane in the middle of your lesson and let students determine what impact the weather systems would have on the path of that airplane. Would they want to fly through the path of an oncoming thunderstorm? Or would a small airplane get bounced around too much in wind gusts and heavy rain?

What is weather? The sun heats the earth unevenly, creating air masses (or regions of air) of varying density, and causing air to circulate over the globe. This heating, along with other factors, also develops areas of relatively high and low pressure. Air tends to flow from areas of high pressure to areas of low pressure, which we experience as wind.

**DEFINITION**

**Frictional force**: The surface of the Earth exerts a frictional drag on the air blowing just above it. How much friction changes with differences in terrain and whether or not the wind blowing has to slow down or change direction to move up, down and around any trees, mountains, etc.

High or low pressure is typically depicted on weather maps as H’s and L’s. Generally, good weather is associated with highs, while poor weather is often found in the lows. If you watch the weather forecasts on television or download weather maps from the Internet you can compare where the H’s and L’s are positioned to where the rain or snow is falling—and often make a connection.

Wind causes air masses to move, and they encounter other air masses that have different characteristics. The boundary between
How does the weather affect flying?

Two air masses is called a front. Weather along fronts may be hazardous to pilots because of the clouds, precipitation, and turbulent air (turbulence) that it can produce. A cold front is where a cold air mass displaces warmer air. A warm front is where warm air displaces colder air. Stationary fronts have no movement.

Temperature, wind, and ambient air pressure change as a front passes by.

Pilots watch the areas of high and low pressure and the movement of fronts to determine what the weather will be like for an upcoming flight. In particular, they look at the clouds, precipitation, wind, and convective activity associated with the weather patterns to make the decision to fly or not.

DEFINITION

**Windshear:** A quick change in the speed and/or direction of wind.

You know convective activity if you’ve ever witnessed a thunderstorm. Heating of the earth’s surface also causes clouds to build if enough moisture is present in the air. When conditions are ripe, clouds tower into thunderstorms, sending heavy rain, hail, strong gusty winds, and sometimes tornadoes, into the area covered by the storm. Thunderstorms are dangerous for airplanes because they combine a number of hazards into one area.

Precipitation, in the form of rain, snow or sleet, can determine whether or not a pilot is able to proceed. Heavy rain can reduce visibility. Snow can block engine air intakes, affecting the engine performance. Water droplets adhere to the airplane in the form of ice, changing both the weight and the shape of the wings and other components, decreasing the airplane’s ability to produce lift. Wind affects the airplane’s speed over the ground, and also may create turbulence or wind shear. Turbulence caused by gusty winds can range from uncomfortable bumps to severe jolts that render the airplane uncontrollable.
**TEACHERS:**

From this activity, students will learn how to glean the basics from weather forecasts and try to predict how the weather will change in the near future.

**MATERIALS:**
Weather charts for a five-day period.

Current surface analysis charts and forecasts can be found at [http://adds.aviation.weather.gov/progs](http://adds.aviation.weather.gov/progs) or go to [www.intellicast.com](http://www.intellicast.com) and click on “Current Surface Analysis” for current conditions of click on the “US Weather” tab and “Surface Analysis” for more options.

Other free sites include the National Weather Service at [www.nws.noaa.gov](http://www.nws.noaa.gov) or the Weather Channel at [www.weather.com](http://www.weather.com).

**TO DO IT:**
Meteorologists use complex models involving physics and mathematics to predict the weather. But they also consult weather maps that are available to you to make a rough estimate of what the future weather holds. They often look at surface analysis charts, which show the conditions at a given time. By looking at several days’ worth of maps, you can look at how the weather has moved from one place to another, how it appears to build or dissipate, and how that weather may have affected pilots flying in that region. You also can take a guess at what the weather will bring to you in the next few days.

- Print out the surface analysis charts (or current conditions maps) for five days in a row from the web sites listed above.
- On the first chart, identify the areas of high and low pressure, and the fronts depicted on the chart. Cold fronts are in blue, and marked with triangles; warm fronts are in red, and marked with half circles.

- Where are the areas of precipitation associated with each front? Each low?

- Now do the same for the next four days’ worth of charts. How are the fronts moving? What happens to the highs and lows as they move?

- Wind tends to parallel a frontal boundary ahead of the front, and pushes from behind a front once the front passes. Can you mark on the chart the direction you think the wind is blowing in each case? Assuming the average general aviation airplane can’t operate safely in winds above 30 knots (34 mph), is the wind too strong for a small airplane to fly?

- Spot your city or town on the chart. What has the weather been like in your area during the days for which you have charts? How does that weather correlate with the highs and lows and fronts you see on the chart?

- Based on the charts, what would you expect the weather to be like tomorrow? Test your forecast by writing it down and comparing it to tomorrow’s actual weather.
An aeronautical chart for part of Kansas.
**LEARNING OBJECTIVE:**
- Students will be able to correctly perform basic flight planning tasks including temperature conversions, weather report decoding, time/speed/distance calculations, and fuel burn rates

**CORE SUBJECTS: MATHEMATICS, GEOGRAPHY**

**PROPER PLANNING PREVENTS POOR PERFORMANCE**—and that’s especially true when it comes to planning a flight! Pilots spend quality time before every flight researching the information they need to make that flight safe—and more fun. They answer questions such as: At what airport should I land? How long are the runways? Can I get fuel? And, most important: Is there a good restaurant at the airport?

To explore the nuances of flight planning, we’ll look at two comparative flights from the Wright Brothers home of Dayton, Ohio, to the area of the first powered flight, near First Flight Airport, North Carolina.

We’ll plan one flight using approximate data for the *Wright Flyer*, the very first powered airplane to make a controlled flight. We’ll take some liberties here; for instance we will assume that the aircraft could structurally make the trip, that it had enough fuel on board for the trip, and that it could reach an altitude sufficient for all terrain clearance. An identical flight will be planned using approximate data for a Piper Archer, a popular four-seat, single-engine airplane.

From these two flight-planning examples, we introduce the students to the concepts of temperature conversion, working with aircraft groundspeed, wind direction and speed, distance to travel, weather, fuel usage, and other aviation issues relating to math and science.
A student pilot uses a course plotter to mark a flight path.
TEACHERS:
From this activity, students will apply the basics of flight planning like a general aviation pilot.

MATERIALS:
Calculator

TO DO IT:
1. Pilots measure temperature in degrees Celsius rather than Fahrenheit. The following formula is used to convert from one to the other.

\[ ^\circ C = \frac{5}{9} \times (^\circ F - 32) \]

Calculate the following temperature in degrees Celsius:

(a) 32° F  
(b) 100° F  
(c) 54° F  
(d) 88° F

2. Pilots often need to squeeze a great deal of information into a small space. Here is an example of a weather report for pilots:

METAR KMGY 052020Z AUTO 03016G23KT 3SM BKN004 OVC014 30/22 A2990

What does it all mean? Let’s break it down for you.

METAR KFFA 102107Z 01005KT 10SM 26/16 A3012

Can your students translate the following weather report? When you have a pilot visit your classroom, ask her to bring a weather report for the day for the students to practice.

METAR KFFA 102107Z 01005KT 10SM 26/16 A3012

- Greenwich Mean Time (GMT) is international time, the basis of the world time clock. It helps eliminate confusion across multiple time zones. It is called Zulu Time in aviation and other applications. Greenwich, England, was chosen as “zero hour” because it is latitude 0 degrees 0 minutes 0 seconds. If you live in the east, your Zulu Time is GMT minus five hours (four hours for daylight savings time); if you live in the west your Zulu Time is GMT minus eight hours (or seven hours for DST). So if you’re in New York City at its noon, your Zulu Time is 1700Z (or 1600Z for DST). Because Zulu Time is based on a 24-hour clock, if it’s 5:00 PM (DST) in New York City, that would be 2100Z (5 PM is 1700 hours so it’s 21 minus 4). GMT is also known as UTC (coordinated universal time). For more information see http://www.greenwichmeantime.com.
3. Pilots measure flight distance in nautical miles as well as statute miles that we use on the ground level. One nautical mile (nm) equals 1.15 statute miles; so one nautical mile per hour (knots) equals 1.15 statute miles per hour (mph). Translate the following distances:

<table>
<thead>
<tr>
<th>To knots:</th>
<th>To mph:</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) 200 mph</td>
<td>(c) 76 knots</td>
</tr>
<tr>
<td>(b) 100 mph</td>
<td>(d) 100 knots</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>To statute miles:</th>
<th>To nautical miles:</th>
</tr>
</thead>
<tbody>
<tr>
<td>(e) 50 nm</td>
<td>(g) 270 miles</td>
</tr>
<tr>
<td>(f) 100 nm</td>
<td>(h) 25 miles</td>
</tr>
</tbody>
</table>

4. Dr. Ivan M. Speedy just bought a Piper Archer that can fly at 120 knots. W. A. Tooslo has a vintage Wright Flyer that flies at 32 mph. They are both planning to leave at the same time and fly to the airport in Dayton, Ohio. If Dr. Speedy lives 300 nautical miles away, and Mr. Tooslo lives 170 nautical miles away, who will arrive first?

5. Before departing Dayton, we need to decide what runway we are going to use. Runways are numbered according to magnetic degrees with one zero removed (see module 9 for a full explanation). If Dayton has runways 2 and 20, that means the runways are facing 20 and 200 degrees. We want to take off into the wind. Using the weather report from question # 2, what runway do we want to use?

6. Once we get into the air, we fly 110 knots at a heading of 120 degrees to get to First Flight airport. If the wind is coming from 300 degrees at 30 knots, what heading do we need to take in order to be on course? What will our speed be?

7. The Piper Archer burns 9 gallons per hour and holds 48 gallons of fuel. Will we be able to make the trip nonstop? If not, how far into the trip will we have to refuel? If the Wright Flyer burns 1 gallon per hour and holds 1 gallon in its fuel tank, how many fuel stops will it need to make along the route?

8. We have been traveling at a good rate of speed, but now the winds have shifted. The wind is now 90 degrees at 10 knots. In what general direction will we need to turn to stay on course?

9. Phew! First Flight Airport is finally in sight. We tune in the radio to get the weather report and this is what it says:

   "Winds are 260 at 5, visibility is 10 miles; temperature is 25 C, dew point 16 C. Altimeter is 30.02."

   If First Flight airport has runways 4 and 22, on which should we land?

   Congratulations! We made it! We have come a long way since 1903. Let’s go refuel, have some lunch, and head on back to Ohio! Let’s see, what runway are we using again…?
LEARNING OBJECTIVES:
- Students will be able to identify the different legs of a traffic pattern
- Students will be able to determine which runway a pilot would select for landing by calculating the crosswind angle and predicting its effect on the airplane

CORE SUBJECTS: GEOMETRY, EARTH SCIENCE, GEOGRAPHY

WHAT IS A TRAFFIC PATTERN?
Almost everyone has heard of airport traffic patterns, but until they become pilots few know what they are. Years ago it was recognized that, without some sort of consistent arrival and departure procedures, the risk of collisions at airports was significant, especially at airports without operating control towers. What evolved was a standard airport traffic pattern formed as a rectangle around the runway in use.

Just as there are “rules of the road” for driving a car, there are rules for how airplanes fly. This is especially important at an airport where the traffic can be very congested and confusing if there were no rules. Common to most airports, pilots fly a full traffic pattern that follow a rectangular path with five typical “legs.”

The legs start with the upwind leg, which runs parallel to the runway in the same direction you will land, followed by the crosswind leg that runs perpendicular to the runway, followed by the downwind leg that again runs parallel to the runway but in the opposite way you will land, followed by the base leg, which again runs perpendicular but on the end of the runway you will touch down, and finally the final leg that takes you on a straight line to the runway and your landing. Unless otherwise directed, all turns in a standard traffic pattern are made to the left.

Finding the runway specified by the control tower for landing is surprisingly easy, because runway numbers are selected to match the airplane’s compass heading on landing. Simply take the compass heading and delete one zero to find the runway number. For example, a pilot approaching Runway 27 would be landing in a westerly direction, and therefore would see 270° displayed on the magnetic compass.
Approaching that same runway from the opposite direction, however, you would see “9” painted on the runway, and 090° on your compass. That’s because there’s always a 180° difference in numbers on each end of a runway. (The runway in this example would be known as “Runway 27/9.”)

In most cases, the runway in use is selected to allow the pilot to land most directly into the wind since it shortens the overall landing distance. So, if the wind is blowing from the west in this example, the pilot will want to land on Runway 27. If it’s from the east, Runway 9 is preferable. And, if the wind is from the south? Runway 18 would be preferred, if there is one; otherwise, the pilot will need to make a “crosswind landing.”

Note: adapted from “You Can Fly!” by Gregory N. Brown and Laurel Lippert
MATERIALS:
Big pieces of chalk
Protractor/Compass
Open areas of concrete or asphalt away from traffic, such as a corner of the parking lot
Copies of this sheet with traffic pattern diagram (from excerpt)

TO DO IT:
- Divide students into teams of three or four.
- Each team gets chalk with which to draw a runway on the concrete.
- Now draw a traffic pattern using the picture on page 45 as a guide.
- Label each leg of the pattern, and mark the runway numbers on the runway.
- Figure out what direction the wind is coming from. If the wind is calm, pick a runway direction, and practice walking the pattern, climbing, turning, leveling off, and descending as an airplane would to land.
- Draw another runway that intersects the first. You can use a protractor to measure the angles the two runways at which the two runways cross each other and the angle at the wind crosses a given runway. This translates into the amount of crosswind that the pilot will need to manage during landing.

QUESTIONS:
1. On what leg is the airplane moving the...
   a. fastest over the ground?
   b. slowest over the ground?
2. Why would a pilot want to land into the wind?
3. How would a crosswind affect the ground track of the airplane in the traffic pattern?
4. What happens when there is more than one airplane coming in to land? Not all airports have control towers, so how do you think the pilots would sort it out?

Note: Adapted from “Women/Leaders Take Flight” seminar, presented by Linda Castner.
A pilot flies over the runway in Kansas City, Missouri, before landing.
LEARNING OBJECTIVE:
- Students will “fly” an airport traffic pattern utilizing a computer flight simulator and aeronautical navigation charts

CORE SUBJECTS: COMPUTER SCIENCE, GEOGRAPHY

HOW MANY HOURS OF FLYING TIME
have your students “logged” so far? The answer may surprise you. One of the first popular games designed for personal computers was the flight simulator program developed in the early 1980s and made famous by Microsoft's® Flight Simulator. You may even have a similar program on your computer at home. Heck, maybe your ace flying is what prompted you to pick up this handbook.

Have you ever wondered how much flying on the small screen relates to real flying? Quite a bit, in fact. The U.S. Navy, in a study in the late 1990s, determined that it saved its new pilots several hours of training time in expensive aircraft by giving them copies of Microsoft® Flight Simulator for practicing maneuvers and scanning instruments. You and your students can do the same thing. It helps to have a plan though. You can’t just barrel around, hoping to gain some piloting prowess out of the virtual blue sky.

Can students fly without leaving the classroom?

TEACHERS
This life-like cockpit photo is from a flight simulator program.
TEACHERS:

From this activity, students will learn how computer flight simulator programs relate to real-world flying. Students will learn how to scan instruments for information while simultaneously controlling the flight of the airplane with their hands. They will get an appreciation for the challenges and the excitement of flying and improve their hand-eye coordination in the process.

If you do not have access to a flight simulator program, ask a local pilot if he or she would be willing to make a donation to your school’s computer lab. Pair this activity with the module on runways and traffic patterns. It helps for students to have learned the basics of traffic patterns before attempting to fly the simulator airplane.

MATERIALS:
Flight simulator program for PC or Mac
Joystick (airplane yoke not required)
Aeronautical chart of your local area, including nearest airport, if available

TO DO IT:

► Load your favorite airplane—or a trainer aircraft like a Cessna 172 or Piper Warrior—and search for your local airport in the database. Set that airport as your launch point.

► If available, access the checklists within the program to start the engine and taxi out to the runway. (What does the local weather tell you about the winds? Can you figure out which runway would be preferred?)

► As you accelerate down the runway, look at the airspeed indicator and note the speed at which you lift off into the sky.

► Climb straight ahead to 500 feet above the ground—check your altimeter to see when you’ve reached that altitude—and push the nose over a little to level-off so you can check for traffic in front of you.

► Continue your climb and begin a left turn, in a bank of about 30 degrees (using the attitude indicator), to a heading 90 degrees less than the runway heading. You’ll need the heading indicator to know for sure when you get there (e.g., from Runway 27 turn “left to 180 degrees”).

► Depending on the graphics, you should be able to look at your map and pick out features on the ground like bodies of water. Most pilots fly using these ground references rather than fixating on the heading indicator. Keeping your eyes focused outside the cockpit helps you see other traffic (airplanes) before they come too close.

► Once you reach 1,000 feet above the ground, level off your altitude. You should be ready to turn 90 degrees to the left again, for your downwind leg of the traffic pattern. Again, depending on the program, you may be able
**ACTIVITY: Flight sim jockey**

to switch views to see out your left window—the runway will be passing off your left wing in a couple of moments.

- Fly down the runway on the downwind leg, until the runway is about a mile and a half behind you, over your left shoulder. Lower your flaps 10 degrees.

- Using the tachometer, pull the power back to about 1,800 rpm and hold the nose level. Let the airspeed come down to about 85 knots, and lower your flaps another 10 degrees.

- Turn 90 degrees left again for the base leg, and continue your descent at 500 feet per minute (fpm) using the vertical speed indicator.

- When you are almost perpendicular to the runway, after a few seconds, turn the last 90 degrees to the final leg of the approach, keeping about 85 knots on the airspeed indicator.

- Lower your flaps another 10 degrees so now you have flaps extended a full 30 degrees. Let the airplane slow down to 70 knots.

When you touch down, you’ve successfully completed your first virtual traffic pattern—one of the most challenging parts of learning to fly. If you want more, check out the training modules within your favorite flight sim game, or check out sim sites on the web for add-on aircraft, scenery, and scenarios.
LEARNING OBJECTIVES:
▶ Students will research and analyze the accomplishments of a significant person in aviation history

CORE SUBJECTS: HISTORY, SOCIAL STUDIES, RESEARCH

EVERY STUDENT NEEDS A HERO, someone to look up to, someone who can teach them the lessons of life by tackling its adventures and overcoming its challenges. As a teacher, you do that every time you step into a classroom. Exploring the world of aviation also provides ample opportunities to highlight the extraordinary pioneers—scientists, mathematicians, inventors, builders, and of course, pilots—who laid the groundwork for modern flyers.

STUDENTS CAN FIND OUT MORE ABOUT THESE PILOTS AND PIONEERS AND THEIR INDIVIDUAL ACCOMPLISHMENTS AND CONTRIBUTIONS TO AVIATION FROM YOUR SCHOOL LIBRARY OR ON THE INTERNET.

Leonardo da Vinci (1452-1519) was the first person to study the problems of flight scientifically. He was fascinated with flapping-wing aircraft called ornithopters, which use the same principles of flight that birds use. He also conceived potential designs for helicopters, propellers, and a parachute.

Sir Isaac Newton (1643-1727) developed theories of motion that formed the basis for principles of flight centuries later.

Daniel Bernoulli (1700-1783) developed one of the underlying principles of airplane wing design, the Bernoulli Effect, in which any increase in the velocity of a horizontal fluid flow results in a decrease in the static pressure.

Sir George Cayley (1773-1857) is known as the “Father of Modern Aviation.” He formulated the basic principles of aeronautics upon which modern flight is founded. Cayley built and flew the world’s first practical and successful airplane—a model glider—in 1804.

Wilbur (1867-1912) and Orville Wright (1871-1948) invented and built the world’s first successful airplane and made the first controlled, powered and sustained heavier-than-air manned flight at Kitty Hawk, North Carolina on December 17, 1903.

Florence “Pancho” Lowe Barnes (1901-1975) organized the Women’s Air Reserves in 1934 to fly aid to victims of national emergencies. She also established the Civilian Pilot Training program.

See an expanded list of aviation pioneers at www.aopa.org/path under “Classroom Tools”.

www.aopa.org/path • For Teachers
Who are the pioneers and heroes of aviation?

**Harriet Quimby (1875-1912)** was the first American woman to earn a pilot’s license and was the first woman to fly across the English Channel.

**Charles Lindbergh (1902-1974)** was best known for accomplishing the first solo, non-stop transatlantic flight from New York to Paris in 1927. He covered the distance of 3,610 miles in 33 hours, 30 minutes.

**Amelia Earhart (1897-1937)** was the first woman to fly solo across the Atlantic Ocean, and the first woman to fly nonstop across the U.S.

**Bessie Coleman (1892-1926)** was blocked from learning to fly in the U.S. so she went to Europe. In 1921 “Queen Bess” became the first black woman ever to earn a pilot’s license. She returned to the U.S. and began to teach other African-Americans how to fly.

**Clyde Cessna (1879-1954)** launched the aircraft manufacturing company bearing his name in 1927. Cessna produced its 150,000th single-engine piston aircraft in July 2004.

**William T. Piper (1881-1970)** was considered “the Henry Ford of aviation.” He mass produced affordable aircraft and popularized the use of airplanes as a method of transportation.

**Chuck Yeager (1923-)** was the first pilot to exceed the speed of sound in level flight, which he accomplished in a Bell X-1 in 1947.

**Willa Brown (1906-1992)** was an aviator, educator, and activist. She helped establish the first all-black flying school, which helped train pilots for World War II. She was the first African-American woman to earn a commercial pilot certificate.

**The Tuskegee Airmen**, or the 99th Fighter Squadron and 332nd Fighter Group, were composed of African-American pilots who fought with great success in World War II—they never lost a bomber under their escort to enemy fighters.

**Elwood R. "Pete" Quesada (1904-1993)** developed the concept of close air support for military ground forces and literally wrote the book in 1943 for the Army on how to employ air power. He was the first head of the Tactical Air Command and one of its few Hispanic three-star generals. Quesada was the first head of the Federal Aviation Administration.

**Neil Armstrong (1930-)**, a civilian test pilot and NASA astronaut on the Apollo 11 mission, was the first person to set foot on the moon in July 1969.

**Alan (1962-) and Dale Klapmeier (1963-)** founded Cirrus Design corporation in 1984, which would go on to certify the first single-engine production airplane to have a whole-aircraft parachute recovery system.

**Eileen Collins (1956-)** was the first woman to pilot a space shuttle, and the first to be selected as commander of a space shuttle mission.

See an expanded list of aviation pioneers at [www.aopa.org/path](http://www.aopa.org/path) under “Classroom Tools.”
ACTIVITY: Who in the aviation world?

TEACHERS:
Use the names below as sample subjects when teaching students basic research skills. Add pilots or aviation innovators to your lesson plan for different periods in history. See an expanded list of aviation pioneers at www.aopa.org/path under “Classroom Tools.”

Leonardo da Vinci  
Sir Isaac Newton  
Daniel Bernoulli  
Sir George Cayley  
Florence “Pancho” Lowe Barnes  
Wilbur and Orville Wright  
Harriet Quimby  
Charles Lindbergh  
Amelia Earhart  
Bessie Coleman  
Clyde Cessna  
William Piper  
Chuck Yeager  
Willa Brown  
The Tuskegee Airmen  
Elwood R. 'Pete' Quesada  
Neil Armstrong  
Alan and Dale Klapmeier  
Eileen Collins

DEVELOP A LIST OF QUESTIONS FOR STUDENTS TO ANSWER. YOU MAY WANT TO INCLUDE THE FOLLOWING:

► Which aviator did you choose to research?

► What contribution did this person make to aviation?

► Why did you select this person? What personal qualities or actions did you find most worthwhile?

► Did this person overcome some obstacle to accomplish whatever they did? If so, what was it?

► For inventors, how is whatever this person invented or discovered used in flying today?

► If you could invent something, what would it be and why?

► If you could be first in doing something, what would you do and why?

► Think of an invention for aviation and explain its benefits and challenges.

MATERIALS:
Internet search engines, school library or media center resources, magazines, newspapers, any and all research sources available.

WHAT TO DO:
► Have each student identify a pilot or aviation pioneer in whom they have some interest.

► Ask each student to research that individual and provide an oral or written report back to the class.
Orville and Wilbur Wright, pictured above with their Wright Flyer, will forever be legends of aviation worldwide.
Module 1 – Page 17
1. Papa India Lima Oscar Tango
2. Alpha India Romeo Papa Lima Alpha November Echo
3. Sierra Charlie Hotel Oscar Oscar Lima
4. As appropriate to school
5. As appropriate to school
6. As appropriate to school
7. November Five Two Five Eight Yankee
8. November One One Two Whiskey November
9. November Niner Niner Mike Sierra
10. November Niner Seven Uniform Alpha

Module 6 – Page 36
1. 110 knots
2. 3,200 feet
3. Yes, a right turn; both the attitude indicator and the turn coordinator show this.
4. The airplane is descending. The attitude indicator shows a slight downward pitch and the vertical speed indicator is showing a 500 ft/min descent.
5. Heading 040 (reference the heading indicator)
6. Since the airplane is in a right turn, the heading will be changing steadily.
7. Since the airplane is in a descent and power has not been adjusted, the airspeed will increase (much like a car going downhill).
8. It will take 2 minutes. The vertical speed indicator shows a 500 ft/min descent; 1000 ft divided by 500 ft/min = 2 minutes.

Module 8 – Pages 43-44
1. (a) 0°C (b) 37.7°C (c) 12°C (d) 31°C
2. Aviation routine weather report for First Flight Airport, 10th day of the month, 9:07 Zulu; wind 10 degrees at 5 knots; visibility 10 statute miles; sky clear below 12,000 feet; temperature 26 degrees Celsius, dew point 16 degrees Celsius; barometer 30.12 inches of mercury
3. (a) 174 kts (b) 87 kts (c) 87 mph (d) 115 mph (e) 58 miles (f) 115 miles (g) 235 nm (h) 22 nm
4. Dr. Speedy will arrive in 2 and a half hours; Mr. Tooslo will arrive in 6 hours and 4 minutes.
5. Runway 2
6. Same course (the wind is directly behind us), 140 kts
7. Piper Archer: 48 gallons, 9 gallons per hour, it will make it. Wright Flyer: 1 gallon, 1 gallon per hour, it must refuel at least every hour.
8. To the left or east.
9. Runway 22

Module 9 – Page 47
1. (a) On the downwind leg, because the wind pushes the airplane from behind. (b) Groundspeed is slowest flying into wind on the final approach.
2. Just as a person gets pushed back or slowed down when walking into the wind, an airplane slows when wind is coming directly at its front. A slower groundspeed at touchdown means the airplane can stop in less runway.
3. Since wind pushes the airplane from the side when the airplane flies across the wind, the airplane’s track over the ground is angled as well. Pilots correct for this by pointing the nose of the airplane into the wind a few degrees.
4. Pilots use the radio to talk to each other, giving position reports and letting other pilots know what they intend to do. Regulations stipulate which aircraft have the right of way, depending on what kind of aircraft it is and where the aircraft are in the traffic pattern.
AOPA provides materials at no cost directly to pilots and teachers. Download the following handouts from AOPA at www.aopa.org/path.

- Choosing a Flight School
- How Safe is It?
- Take 'Em Flying
- What is General Aviation?
- What You'll Fly

You Can Fly! by Gregory N. Brown and Laurel Lippert is an excellent reference for students (and teachers) who want to learn more about general aviation. Copies may be ordered from Aviation Supplies & Academics. Contact: 800/426-8338; www.asa2fly.com

Here are some pilot favorites you can suggest to young people who want to learn more about aviation:

- Biplane, Richard Bach
- A Gift of Wings, Richard Bach
- Bax Seat: The Log of a Pasture Pilot, Gordon Baxter
- Flying Carpet: The Soul of an Airplane, Gregory N. Brown
- Flight of Passage, Rinker Buck
- Weather Flying, Robert Buck
- Conquest of Lines and Symmetry: Aerobatics, Duane Cole
- Cannibal Queen, Steven Coonts
- Going Solo, Roald Dahl
- I Could Never Be So Lucky Again, James Doolittle and Carroll Glines
- Fate is the Hunter, Ernest K. Gann
- Zero Three Bravo, Mariana Gosnell
- Flying America’s Weather, by Thomas A. Horne
- Stick & Rudder, Wolfgang Langewiesche
- West with the Night, Beryl Markham
- Listen! the Wind, Anne Morrow Lindbergh
- Spirit of St. Louis, Charles Lindbergh
- We, Charles Lindbergh
- Apollo 13, James Lovell and Jeffrey Kluger
- Wind, Sand, and Stars, Antoine de St. Exupery
- Weekend Pilot, Frank Kingston Smith
- Fly the Wing, James Webb
- The Right Stuff, Tom Wolfe
- Yeager, Charles Yeager et al.

THANKS FOR JOINING US ALONG THE PATH TO AVIATION!

Whether you’re a pilot or an educator—or both—you’ll find this Pilot and Teacher Handbook is designed to highlight the connections between aviation and everyday classroom topics. Very few young people are exposed to aviation unless an adult with a passion for flying shares that experience and opens the door for exploration and learning. AOPA, the Aircraft Owners and Pilots Association, is proud to provide this handbook to foster a sharing of knowledge and help make you do just that.

The Aircraft Owners and Pilots Association (AOPA) represents the general aviation industry and its pilots. With more than 415,000 members, AOPA is the largest and most influential aviation association in the world. AOPA has proudly served its members through advocacy, education, and many other services since 1939.

AOPA would like to thank Jim and Karli Hagedorn for their generous sponsorship of the PATH to Aviation.
